Abstract
The treatment equimolar quantities of carboxylic acids with acid chlorides in the presence of ZnO brings about highly efficient unsymmetrical anhydrides at room temperature in solvent-free condition. Reactivity trends favored formation of the product using both electron deficient and rich aryl acids and acid chlorides.

Keywords: ZnO; Unsymmetrical anhydrides; Solvent-free conditions; Carboxylic acid

1. Introduction
Because of the wide applications of carboxylic acid anhydrides for the preparation of many other functional groups such as amides, esters, peptides [1] and as acylating agents, the development of highly selective and environmental friendly synthetic methods of carboxylic acid anhydrides has been of interest. Many useful methods have been reported in the literature for the synthesis of symmetrical carboxylic acid anhydrides [2-17].

However, to our knowledge only a few methods have been reported for the synthesis of asymmetrical carboxylic acid anhydrides by the reaction of an acyl halide and a carboxylic acid [18]. The synthesis of asymmetrical anhydrides needs reagents, which are unstable, not commercially available, not easy to handle, not reusable or else need lengthy workup. Srivastava and Kabalka [18c] reported the use of CoCl₂ as a catalyst for synthesis of anhydrides. Although this catalyst removes the need for difficult reagents, at the end of the reaction the separation of the cobalt salt proves a problem. Recently, Leadbeater and co-workers [18b] reported the use of a polymer-supported cobalt phosphine complex catalyst for anhydride formation. This catalyst can be reused and appears to be a good procedure, but there are several factors limiting its applications, for example, no commercially available catalyst, use of toxic organic solvent, using a nitrogen bubble flow, and long reaction time. Metal oxide catalysts have rapidly become an area of intense research activity.

One of the key advantages of using metal oxide catalysts is the ease of separation from the product mixture at the end of a reaction. As well as allowing for more rapid purification of the product mixture, this means that the metal oxides can be reused in subsequent reactions.

2. Results and discussion
In continuation of our interest in the application of metal oxides as catalysts in organic synthesis [19], in this paper, we would like to report the ZnO as an effective catalyst for the synthesis of unsymmetrical carboxylic acid anhydrides rapidly at room temperature, in high yield under solvent-free conditions (Scheme 1).

Scheme 1.

To exploit a simple and suitable condition for synthesis of anhydrides, the reaction of benzoyl chloride with benzoic acid was studied under a variety of conditions via TLC and \(^1\)H NMR spectroscopy (Table 1).

a) Isolated yields

According to Table 1, initially a mixture of benzoic acid 1a (1mmol) and benzoyl chloride 2a (1mmol) was stirred at room temperature for 5 min. in the presence of ZnO (5 mol %) in solvent-free conditions. The reaction occurred to generate corresponding benzoic anhydride 3a in 30% yield. Further, the amount of the catalyst versus reaction yields of product was studied. An increase in the amount of ZnO to 100 mol% led to an increase in the yield of product without significantly affecting reaction times. Then, to find safe reaction conditions, various solvents were studied. As shown in Table 1, entries 5-9, using several organic solvents did not affect either reaction time or yields. So, the best reaction conditions are using 100 mol% of the catalyst, at room temperature and no solvent. To illustrate the need for catalyst for these reactions, an experiment was conducted in which the reaction of benzoyl chloride 2a with electron withdrawing substituted benzoic acids (entries 2-6), as well as of electron donating substituted benzoic acid (entry 7) showed good results. It was very exciting to find that fatty acids such as stearic acid and 1-aminoundecanoic acid (entries 10, 11) reacted very rapidly in the presence of ZnO to afford the corresponding anhydride in high yields. This procedure is also good enough for the preparation of anhydride from dicarboxylic acids, diacid chlorides, and cyclic acid or acid chlorides (entries 12-15). It is interesting to note that benzene sulfonic acid 1n reacted with benzoyl chloride to afford the corresponding sulfonic acid anhydride in good yield (entry 18). However, this method was not suitable for the conversion of phosphonic acids or thiocarboxylic acids. As shown in Table 2, the reactions are remarkably clean, and no chromatographic separation is necessary to get the spectra-pure compounds except in some cases (Table 2, entries 5, 6, 8, 9, and 13-16) where some starting materials remained, the conversion being less than 90%.

A mechanistic proposal for the role of ZnO as the catalyst is shown in scheme 2. The ZnO has Lewis acid sites (Zn⁡⁺⁺) and Lewis basic sites (O⁡⁻⁻) [20]. Lewis acid sites (Zn⁡⁺⁺) of ZnO are coordinated to the oxygen of the carbonyl groups in both acid and acid chloride, resulting in the increased reactivity to give intermediate I. After losing a molecule of HCl the product was obtained.

Finally, In order to show the accessibility of the present work in comparison with some other catalysts reported previously, we summarized some of the results for the preparation of benzoic anhydride 3a in Table 3. This shows that ZnO is the most efficient catalyst with respect to the reaction time and temperature and exhibits broad applicability in terms of yield.

3. Experimental

Starting materials were obtained from Fluka Company. ¹H NMR and ¹³C NMR spectra were measured on Bruker Advance DPX FT 250 and 62.9 MHz spectrometry with TMS as an internal standard. IR spectra were obtained on a Perkin-Elmer or FTIR-800 instruments. Mass spectra were obtained on a Shimadzu GCMS0QP 1000EX at 20 and/or 70 eV. Elemental analyses were performed on Thermo Finnigan, Flash EA 1112 series micro analyzer by the head of the CHN lab.

3.1. General procedure

3.1.1. General procedure

Carboxylic acids 1 (1 mmol) were added to ZnO which had been dried in an oven overnight at 100 °C (powder 0.08 g ,1mmol); after a few minutes, carboxylic acid chloride 2 (1 mmol) was added dropwise at room temperature and stirred with a magnetic stirrer. The progress of the reaction was monitored by TLC. The solid mass was then eluted with dichloromethane (CH 2Cl2) or EtOAc. The organic solvent was then washed with H 2O (2×10 mL) and a saturated solution of NaHCO 3 and dried over anhydrous Na 2SO4. After removal of the solvent, the pure products 3a-d, 3g, 3j-l, 3q, and 3r were obtained. In the case of compounds 3e, 3f, 3h, 3i, and 3m-p, the crude product was purified by silica gel column chromatography (n-hexane:EtOAc, 4:1). The structure of the products was confirmed by ¹HNMR, IR, and compared with authentic samples obtained commercially or prepared by reported methods.

10-Aminodecanoic benzoic anhydride (3k) White solid; m.p: 105 °C; IR (KBr): ν 1720, 1778 (C=O), 987 (C-O) cm -1; ¹H NMR (250 MHz, CDCl3): δ 8.02-8.10 (m, 2H, Ar-H), 7.48 (m, 1H, Ar-H), 7.31-7.45 (m, 2H, Ar-H), 6.14 (bs, 2H, -NH2), 3.34-3.42 (m, 2H, -CH2-NH2), 2.22-2.57 (m ,2H,-CH2CO-), 1.50-1.72 (m, 4H, -CH2CH2CH2CO-), 1.21 (m, 12H, -CH2-C12H25-CO-); ¹³C NMR (62.89 MHz, CDCl3): δ 171.0, 162.3, 134.5, 131.2, 130.5, 128.8, 128.5, 126.8, 40.1, 35.5, 29.6, 29.3, 29.2, 28.9, 26.9, 24.2. 4. Conclusion

In conclusion, we have described a novel and highly efficient solvent-free protocol for synthesis of unsymmetrical anhydride using non toxic and inexpensive ZnO powder. The advantages of this environmentally benign and safe protocol include a simple reaction setup, not requiring specialized equipment, very mild reaction conditions, high product yields, very short reaction times, and the elimination of solvents.
